Erklärung zur Verfassung der Arbeit

Gilbert Fritz
Schlosshofer Straße 49/18

Hiermit erkläre ich, dass ich diese Arbeit selbständig verfasst habe, dass ich die verwendeten Quellen und Hilfsmittel vollständig angegeben habe und dass ich die Stellen der Arbeit - einschließlich Tabellen, Karten und Abbildungen -, die anderen Werken oder dem Internet im Wortlaut oder dem Sinn nach entnommen sind, auf jeden Fall unter Angabe der Quelle als Entlehnung kenntlich gemacht habe.

(Ort, Datum)

(Unterschrift Verfasserin)

Danksagung

Ich danke meinen Betreuern, ao. Univ.-Prof. Dipl.-Ing. Dr.techn. Günther Raidl und Univ.Ass. Dipl.-Ing. Dr.techn. Bin Hu für ihre Unterstützung bei der Erstellung dieser Arbeit durch ihr konstruktives Feedback und ihre Ideen, welche es mir ermöglicht haben, immer neue Aspekte der Problemstellung zu erkennen.

Besonderer Dank gilt meinen Eltern, Franz und Justine Fritz, sowie meiner Partnerin Odnoo und meinen Freunden für Ihre Unterstützung.

Introduction

1.1 Motivation

In order to obey the emerging demand for advanced broadband Internet applications such as video-conferences, high performance computing and others, extensive networks capacities have to be achieved. Links in optical networks operate much faster than their currently available electronic counterparts. Combined with the technique of Wavelength Division Multiplexing (WDM), which permits the simultaneous transmission of different channels along the same fiber [24], these so called Wavelength Routed Optical Networks (WRON's) are promising candidates for providing a flexible transport backbone network [18]. They bring out new problems in coordination of wavelengths usage [6]. One of them is the Routing and Wavelength Assignment Problem (RWA), which consists in routing a set of light-paths and assigning a wavelength to each of them. The variant where all connection requirements are known beforehand and which aims to minimize the amount of used wavelength is called min-RWA and found to be \mathcal{NP} -hard [31].

Assigning wavelengths to one out of many paths for each connection requirement is equivalent to the \mathcal{NP} -hard **Partition Coloring Problem (PCP)** [21], also known as **Partition Graph Coloring Problem (PGCP)** which is subject of this thesis. Given a graph consisting of a clustered set of vertices and a set of edges, the aim is to select one vertex per cluster and for each vertex in the resulting subgraph assign a color in the way that the overall number of colors – which in this context is said to be the chromatic number – is minimized. If each cluster holds only one vertex, the problem reduces to the Standard Vertex Coloring Problem (VCP), which is used for a wide range of applications as scheduling, register allocation, pattern matching and others and has been studied extensively. In contrast, only a few papers have been published on PCP so far.

The aim of this thesis is to explore a solution method that has not been subject of publications on PCP yet, in order to achieve advanced approximation methods.

1.2 Guide to the Thesis

Definitions from graph theory and basic concepts which are required for the analysis of the Partition Coloring Problem are introduced in Chapter 2. Afterwards, Chapter 3 defines the PCP as well as the min-RWA formally and comments their computational complexity. Previous works and related research done so far is presented in Chapter 4. Chapter 5 provides details of the approach developed for the PCP and Chapter 6 presents its experimental results. Chapter 8 summarizes the knowledge achieved within this thesis, brings the considered approach into question and finally proposes a possible further work.

Preliminaries

This chapter introduces theoretical fundamentals like definitions, terms and methods, that are necessary for analysing the Partition Coloring Problem. The presented notations will be used consistently in this thesis.

2.1 Optimization Problems and Complexity

Since this thesis deals with an optimization problem and the analysis of a solution to it needs to consider some complexity theory is an important field of computer science. Some definitions and explanations of optimization problems and complexity are given in this section. For a more detailed insight the reader is referred to [13, 19, 27].

In general an optimization problem is the problem of finding the best solution among all feasible solutions. Depending on whether the variables are continuous or discrete, the optimization problem is said to be a continuous optimization problem or a combinatorial optimization problem (COP). Since the PCP belongs to the latter category, this thesis will not cover further explanations on continuous optimization problems. For information on that topic, the reader is referred to [17, 26]. Most of the following definitions have been introduced in [5, 10].

Definition 1 (Combinatorial Optimization Problem) *A Combinatorial Optimization Problem $P = (S, f)$ can be defined by:*

- *A set of variables $X = \{x_1, x_2, \dots, x_n\}$;*
- *variable domains D_1, \dots, D_n ;*
- *constraints among the variables;*
- *an objective function f to be minimized¹, where $f : D_1 \times D_2 \times \dots \times D_n \rightarrow \mathbb{R}^+$;*

¹Maximizing an objective function f is the same as minimizing $-f$

The set of all feasible assignments is $S = \{s = \{(x_1, v_1), (x_2, v_2), \dots, (x_n, v_n)\} \mid v_i \in D_i, s \text{ satisfies all the constraints} \}$

For each COP P there exists a corresponding decision problem D , i.e. a problem whose output is either *YES* or *NO*. The complexity of D determines the complexity of P .

Definition 2 (Decision Problem) *The decision problem D for a Combinatorial Optimization Problem P asks if, for a given solution $s \in S$, there exists a solution $s' \in S$, such that $f(s')$ is better than $f(s)$: for a minimization problem this means $f(s') < f(s)$ and for a maximization problem $f(s) > f(s')$.*

An important issue that comes up when considering combinatorial optimization problems is the classification problems by their difficulty. To categorize problems into easy and difficult ones, the class of problems that are solvable in polynomial time by a deterministic Turing machine and problems that are solvable in polynomial time by a nondeterministic Turing machine are considered. This thesis prefers to describe the characteristics of \mathcal{P} and \mathcal{NP} at a more intuitive level, rather than formalizing the classes via Turing Machines. An examples for a problem in \mathcal{P} is single source shortest path.

Definition 3 (Complexity class \mathcal{P}) *A problem is in \mathcal{P} iff it can be solved by an algorithm in polynomial time.*

The complexity class \mathcal{NP} is associated with hard problems. \mathcal{NP} stands for “nondeterministic polynomial time”, where “nondeterministic” is a way to express that solutions are guessed. The class \mathcal{NP} is restricted to Decision Problems.

Definition 4 (Complexity class \mathcal{NP}) *A decision problem is in \mathcal{NP} iff any given solution of the problem can be verified in polynomial time.*

The above definition states, that the solutions for problems in \mathcal{NP} do not require to be calculated in polynomial time, but the solutions need to be verified in polynomial time. Therefore $\mathcal{P} \subseteq \mathcal{NP}$ holds (slightly abusing notation by restricting \mathcal{P} to decision problems) [10].

Definition 5 (\mathcal{NP} -optimization Problem) *A COP is a \mathcal{NP} -optimization problem (NPO) if the corresponding decision problem is in \mathcal{NP} .*

As an example the decision variant of the Standard Vertex Coloring Problem (VCP) is considered, which asks whether a graph G is colorable within k colors or not. An algorithm has to verify for each vertex v colored with color c_v , if all its neighbors are colored with a color different to c_v and further count the number of distinct colors to check whether the number of colors is lower or equal to k . This can be done in time $\mathcal{O}(|V|^2)$, where V is the set of vertices.

The VCP and many other optimization and decision problems are at least as difficult as any problem in \mathcal{NP} . These problems are said to be \mathcal{NP} -hard. Giving a polynomial-time reduction from an \mathcal{NP} -hard problem to a particular problem shows that this problem is \mathcal{NP} -hard, too. Such a reduction links the considered problem to the known \mathcal{NP} -hard problem in such a way that if and only if the considered problem can be solved in polynomial time also the \mathcal{NP} -hard problem to which it has been reduced can. [10] To gain a more detailed insight into that topic, the reader is referenced to [33].

Definition 6 (\mathcal{NP} -hard problems) *A problem is called \mathcal{NP} -hard iff it is at least as difficult as any problem in \mathcal{NP} , i.e., each problem in \mathcal{NP} can be reduced to it.*

A lot of optimization problems are \mathcal{NP} -hard but not in \mathcal{NP} . For example, the optimization variant of the VCP, which searches for the minimum chromatic number is clearly at least as hard as its decision variant described above. Since the output is a number rather than a decision, it is not in \mathcal{NP} . \mathcal{NP} -hard problems that are also in \mathcal{NP} are called \mathcal{NP} -complete. Many decision variants of \mathcal{NP} -hard problems like the VCP are \mathcal{NP} -complete.

Definition 7 (\mathcal{NP} -complete problems) *A problem is \mathcal{NP} -complete iff it is \mathcal{NP} -hard and in \mathcal{NP} .*

Informally, \mathcal{NP} -complete problems are the hardest problems in the class \mathcal{NP} . If there is an algorithm that solves any \mathcal{NP} -complete problem in polynomial time, then every problem in \mathcal{NP} can be solved in polynomial time. So far no polynomial time deterministic algorithm has been found to solve one of them.

Theorem 1 *If any \mathcal{NP} -complete problem can be solved by a polynomial-time deterministic algorithm, then $\mathcal{NP} = \mathcal{P}$. If any problem in \mathcal{NP} cannot be solved by a polynomial-time deterministic algorithm, then \mathcal{NP} -complete problems are not in \mathcal{P} .*

Most computer scientists assume that $\mathcal{P} \neq \mathcal{NP}$, although it has not been proven yet. The question $\mathcal{P} = \mathcal{NP}$ is one of the most prominent unresolved questions in the field of complexity theory, since a proof would imply a huge impact on any other discipline in discrete mathematics and computer science.

Nevertheless, for some \mathcal{NP} -complete problems of this class it is possible to develop algorithms that have an average-case polynomial time complexity, despite having exponential time complexity in worst case. For other problems in this class, approximation algorithms can be found that return solutions in polynomial time with a guarantee of a specific solution quality. The development and analysis of approximation algorithms is an important field of research. The following definitions are taken from [34].

Definition 8 (Approximation algorithm) *An α -approximation algorithm for an optimization problem is a polynomial-time algorithm that for all instances of the problem produces a solution whose value is within a factor of α of the value of an optimal solution.*

The α is called approximation ratio or performance guarantee of the α -approximation algorithm. For minimization problems $\alpha > 1$ and for maximization problems $\alpha < 1$ holds. For example, a $1/2$ -approximation algorithm for a maximization problem always returns a solution in polynomial time, that is at least half as good as the optimal solution. For some problems there even exist polynomial time algorithms, whose approximation ratio can be given as parameter. They have so called polynomial-time approximation schemes.

Definition 9 (Polynomial-time approximation scheme) *A polynomial-time approximation scheme (PTAS) is a family of algorithms $\{A_\epsilon\}$, where there is an algorithm for each $\epsilon > 0$, such that A_ϵ is a $(1 + \epsilon)$ -approximation algorithm (for minimization problems) or a $(1 - \epsilon)$ -approximation algorithm (for maximization problems).*

2.2 Graph Theory Definitions

Definition 10 (Graph) A graph is a tuple $G = (V, E)$, where V denotes the set of nodes and $E \subseteq V \times V$ denotes the set of edges. An edge from node i to j is denoted by $\{i, j\}$. We call a graph simple, if it does not contain multiple edges, i.e. more than one edge between the same nodes, or loops, i.e. edges $\{i, i\}$.

Definition 11 (Directed graph) A directed graph or digraph is a tuple $D = (V, A)$, where V denotes the set of nodes and $A \subseteq V \times V$ denotes the set of arcs or directed edges. An arc from node i to j is denoted by (i, j) . We call a directed graph simple, if it does not contain multiple arcs, i.e. more than one arc between the same nodes, or loops, i.e. arcs (i, i) .

Unless declared explicitly, this thesis considers only simple, undirected graphs $G = (V, E)$.

Definition 12 (Directed graph) Given a graph $G = (V, E)$, $G' = (V', E')$ is called a subgraph if $V' \subseteq V$, $E' \subseteq E$ and $E' \subseteq V' \times V'$. If $V' = V$ we call G a spanning subgraph or factor.

Definition 13 (Deletion of a node) Given a graph $G = (V, E)$, $G - v = (V \setminus v, E \setminus \{e \mid v \in e\})$.

Definition 14 (Adjacency and incidence) Two nodes x and y are called adjacent, if they share an edge e , i.e. $\exists e = \{x, y\} \in E$. Two edges e and f are called adjacent, if they share a node x , i.e. $e \cap f = x$. A node v is called incident to an edge e , if $v \in e$.

Definition 15 (Node degree) The degree of a node v in an undirected graph G , denoted by $d(v)$, is the number of edges, that are incident to the node v , i.e. in E there exists an edge $\{v, x\}$. The number of outgoing arcs (v, x) from a node v in a directed graph D is called out-degree and is denoted by $d^+(v)$, the number of ingoing arcs (x, v) to a node v is called in-degree and is denoted by $d^-(v)$.

Lemma 1 (Handshaking Lemma)

$$\sum_{v \in V} d(v) = 2|E|$$

Proof. As every edge $\{i, j\}$ is incident to exactly two nodes, namely i and j , it is counted one time at $d(i)$ and one time at $d(j)$. So the sum over all node degrees is exactly two times the number of edges. \square

Corollary 1 (Directed graph) The number of nodes with odd node degree is even.

Proof. This immediately follows from the handshaking lemma. \square

Lemma 2

$$\sum_{v \in V} d^+(v) = \sum_{v \in V} d^-(v) = 2|A|$$

Proof. As every arc (i, j) has exactly one "in-node" and one "out-node", it follows, that the sum of all out-degrees equals the sum of all in-degrees and hence the number of arcs. \square

Definition 16 (Maximum and minimum node degree) $\Delta(G) = \max\{d(v) \mid v \in V\}$ denotes the maximum node degree in a graph. $\delta(G) = \min\{d(v) \mid v \in V\}$ denotes the minimum node degree in a graph.

Definition 17 (Neighborhood of a node) The neighborhood of a node $v \in V$ is denoted by $N(v) = \{x \mid \{v, x\} \in E\}$. In the directed case the neighborhood consists of all nodes that are reachable from v , i.e. $N(v) = \{x \mid (v, x) \in A\}$.

Definition 18 (Walk) A sequence $v_0, e_1, v_1, e_2, \dots, e_n, v_n$ with $n \geq 0$ is called a walk, if for all v_i with $i \neq 0$ exists an $e_i = \{v_{i-1}, v_i\} \in E$.

Definition 19 (Directed walk) A sequence $v_0, a_1, v_1, a_2, \dots, a_n, v_n$ with $n \geq 0$ is called a directed walk, if for all v_i with $i \neq 0$ exists an $a_i = (v_{i-1}, v_i) \in A$.

Definition 20 (Trail) A sequence $v_0, e_1, v_1, e_2, \dots, e_n, v_n$ with $n \geq 0$ is called a trail, if for all v_i with $i \neq 0$ exists an $e_i = \{v_{i-1}, v_i\} \in E$ and all e_i are distinct.

Definition 21 (Directed Trail) A sequence $v_0, a_1, v_1, a_2, \dots, a_n, v_n$ with $n \geq 0$ is called a directed trail, if for all v_i with $i \neq 0$ exists an $a_i = (v_{i-1}, v_i) \in A$ and all a_i are distinct.

Definition 22 (Path) A sequence $v_0, e_1, v_1, e_2, \dots, e_n, v_n$ with $n \geq 0$ is called a path, if for all v_i with $i \neq 0$ exists an $e_i = \{v_{i-1}, v_i\} \in E$ and all v_i are distinct.

Definition 23 (Directed path) A sequence $v_0, a_1, v_1, a_2, \dots, a_n, v_n$ with $n \geq 0$ is called a directed path, if for all v_i with $i \neq 0$ exists an $a_i = (v_{i-1}, v_i) \in A$ and all v_i are distinct.

Definition 24 (Length of a path) Given a path $P = v_0, e_1, v_1, e_2, \dots, e_n, v_n = P(v_0, v_n)$, the length is the number of edges and denoted by $l(P) = n$, analogously for the directed case.

Definition 25 (Cycle) A cycle is a path, where $v_0 = v_n$.

Definition 26 (Acyclic graph) A graph is called acyclic if it does not contain a cycle.

Theorem 2 Let $W = W(v_0, v_n)$ be a walk, then there is a subsequence $P = P(v_0, v_n) \subseteq W(v_0, v_n)$ such that P is a path.

Proof. We know that for a path holds $v_i = v_j \forall i < j$. Suppose for W holds that $v_i = v_j$ for arbitrary $i < j$. Then $W = v_0, e_1, v_1, \dots, v_i, e_{j+1}, v_{j+1}, \dots, v_n$ is a walk with $i - j$ less edges and W is a subsequence of W . Applying this until $\forall i, j : v_i = v_j$ yields a path from v_0 to v_n . This of course also holds for the directed case. \square

Definition 27 (Network) A network $N = (G, c)$ consists of a graph $G = (V, E)$ and a cost function $c : E(G) \rightarrow \mathbb{R} \geq 0$, which assigns each edge e a nonnegative value c_e . Networks are also called weighted graphs.

Definition 28 (Costs of a graph) The cost c_G of a graph G is the sum of its edge costs, i.e. $c_G = \sum_{e \in E} c_e$.

Definition 29 (Coloring) A coloring is a mapping $v \rightarrow \mathbb{N}^+ \mid \forall v \in V$. Let c_v denote the color assigned to node v . The coloring is feasible, iff $c_x \neq c_y \mid \{x, y\} \in E, \forall \{x, y\} \in E$.

Definition 30 (chromatic number) Let $G = (V, E)$ be a graph. We state that c is a (proper) k -coloring of G if all the vertices in V are colored using k colors such that no two adjacent vertices have the same color. The chromatic number is defined as the minimum k for which there exists a (proper) k -coloring of G .

2.3 Metaheuristics

As defined before, a COP consists of a set of feasible solutions. In almost every case this is of huge size compared to the size of the instance. Solving a COP exactly means finding the optimal solution out of that set. Since for \mathcal{NP} -complete problems no algorithm that performs in polynomial time could be found yet, scientists try to find algorithms that approximate optimal solutions.

In general there exist two classes of approximation methods: construction and improvement heuristics. As its name states, the former construct a solution from scratch by adding components until the solution is complete. Usually these algorithms perform fastest but often return a solution quality that is inferior to the ones returned by improvement heuristics. Used as initial solution for an improvement heuristic, the construction heuristic may return an infeasible solution. Afterwards an improvement heuristic iteratively tries to replace the solution by a better/feasible one that is derived from the current solution.

Improvement heuristics can be divided into two groups, population based and local search based heuristics. [5] The former includes – but is not restricted to – Ant Colony Optimization (ACO), Evolutionary Computation (EC) including Genetic Algorithms (GA) and the second group consists of Iterated Local Search (ILS), Simulated Annealing (SA) and Tabu Search (TS). TS is described in more detail in section 2.5 and as this thesis does not deal with population based algorithms, it excludes further descriptions of this group. The reader is referred to [14].

All these methods form a relatively new group of heuristics and are summed up by the term *metaheuristics*, which was first introduced in [16]. In 1996 Osman and Laporte provided a formal definition of metaheuristics [25]:

Definition 31 (Metaheuristic) A metaheuristic is formally defined as an iterative generation process which guides a subordinate heuristic by combining intelligently different concepts for exploring and exploiting the search space, learning strategies are used to structure information in order to find efficiently near-optimal solutions.

Any COP can be solved by any kind of metaheuristic. The famous no free lunch theorem [35] states, that over all possible problems, there is no heuristic that performs better than any other heuristic including random search. According to the theorem, if a strategy performs better in one subarea, it performs worse in another. By acquiring and including problem specific knowledge, it is possible to develop strategies for classes of problems that perform better than others [8]. In that context, Gebhard defined in [28]:

Definition 32 *Metaheuristic algorithms make no assumptions on the problem and (in theory) can be applied on any optimization problem. They define an abstract order of instructions which lead to improved or feasible solutions. In almost any case these instructions must be implemented using problem specific knowledge.*

2.4 Basic Local Search

Basic local search (LS) is an improvement heuristic that iteratively tries to replace the solution by a better one that is located in an appropriately defined neighborhood structure of the current solution. [5] Algorithm 1 outlines the basic local search procedure.

Algorithm 1: Basic Local Search

Input: A COP $P = (S, f)$
Output: A feasible Solution s

```

1  $s \leftarrow \text{GenerateInitialSolution}(S);$ 
2  $\text{improved} \leftarrow \text{true};$ 
3 while  $\text{improved}$  do
4    $s' \leftarrow \text{Improve}(\mathcal{N}(s));$ 
5   if  $f(s')$  NOT better than  $f(s)$  then
6      $\text{improved} \leftarrow \text{false};$ 
7   else
8      $s \leftarrow s';$ 
9 return  $s$ 
```

Definition 33 (Neighborhood structure) *A neighborhood structure is a function $\mathcal{N} : S \rightarrow 2^S$ that assigns to every $s \in S$ a set of neighbors $\mathcal{N}(s) \subseteq S$. $\mathcal{N}(s)$ is called the neighborhood of s .*

Iteratively improving the solution by choosing the first neighbor $s_f \in \mathcal{N}(s) \mid f(s_f) < f(s)$ for a minimization problem is called *First Fit* (FF), choosing the best neighbor $s_b \in \mathcal{N}(s) \mid f(s_b) < f(x), \forall x \in \mathcal{N}(s)$ is called *Best Fit* (BF). In the basic version of LS, both variants stop if no better solution can be found, which is called a local minimum. As this thesis is about the PCP which is a minimization problem, optimum and minimum are used equivalently.

Definition 34 (Local minimum) *A locally minimal solution (or local minimum) with respect to a neighborhood structure \mathcal{N} is a solution \hat{s} such that $\forall s \in \mathcal{N}(\hat{s}) : f(\hat{s}) \leq f(s)$. We call \hat{s} a strict locally minimal solution if $\forall s \in \mathcal{N}(\hat{s}) : f(\hat{s}) < f(s)$.*

Figure 2.1: Local and global optima

Definition 35 (Global minimum) A global minimum (optimum) of a minimizing combinatorial optimization problem is a solution, such that $f(\hat{s}) \leq f(s), \forall s \in X$. Therefore a global optimum is a local optimum for all neighborhood structures \mathcal{N} .

Stopping at a local minimum results in quite unsatisfactory solutions, therefore methods have been developed to escape from such a local minimum in order to find the global minimum. Figure 9 intends to provide an idea of local and global minima to the reader. A simple technique is to start the LS from different initial solutions repeatedly, which is not very efficient, since the search information from preceding searches is not used. Instead of stopping at a local minimum, metaheuristic algorithms use more complex termination conditions including maximum number of iterations or CPU time.

2.5 Tabu Search

The Simple Tabu Search (TS) outlined in 2, chooses the best fitting solution out of the neighborhood $\mathcal{N}(s)$, which is not held in a short term memory, the so called tabu list. It holds recently visited solutions and is used to prevent cycles. Moreover, since the tabu list causes the algorithm to accept uphill moves, it can help to escape from local minima. Each chosen solution is added to the tabu list, which is of a specified size and therefore the algorithm has to remove solutions from it, which is usually done in a FIFO order. Most implementations of TS – like the one implemented in this thesis – do not store whole solutions, but solution attributes like moves or differences between solutions. The size of the list is a crucial parameter in TS and has to be chosen wisely, since if it is chosen too short the algorithm may stuck in cycles of higher order more likely and if it is chosen too long, the search space is restricted too much. The algorithm

terminates if a specified termination criterion is met.

Algorithm 2: Tabu Search

Input: A COP $P = (S, f)$

Output: A feasible Solution s

```

1  $s \leftarrow \text{GenerateInitialSolution}(S)$ ;
2  $\text{TabuList} \leftarrow \emptyset$  while NOT termination criterion do
3    $s' \leftarrow \text{ChooseBestOf}(\mathcal{N}(s) \setminus \text{TabuList})$ ;
4    $\text{Update}(\text{TabuList})$ ;
5 return  $s$ 

```

2.6 Integer Linear Programming

Linear Programming (LP) or Mathematical Programming is an important field of operations research. Formulating a Linear Program (LP) is a mathematical way to define a COP and consists of defining the following inequations and equations: an objective function, a set of constraints on the variables x and a set of constraints on their domain, which are all inequations. All LPs can be written in the following form:

$$\begin{aligned}
 \max. \quad & c^T x \\
 \text{s.t.} \quad & Ax \leq b \\
 & x \in \mathbb{R}^n
 \end{aligned}$$

For each maximization problem there exists a minimization problem and vice versa, in the way that both problems are equivalent. The following set of equations defines the dual problem to the primal maximization problem:

$$\begin{aligned}
 \min. \quad & b^T y \\
 \text{s.t.} \quad & A^T y \geq c \\
 & y \in \mathbb{R}^n
 \end{aligned}$$

Restrictions on the domain of the variables dedicates the LP into one of the following categories. Be x the set of variables:

1. Linear Program (LP): $x \in \mathbb{R}^n$
2. Integer Linear Program (ILP): $x \in \mathbb{Z}^n$
3. Binary Integer Linear Program (BIP): $x \in \{0, 1\}^n$
4. Mixed Integer Linear Program (MIP): variables can be restricted to different domains

Optimizing the objective function with respect to the constraints means to solve the problem exactly and is in general \mathcal{NP} -hard. It has to be considered that classifying the problem into complexity classes only gives a worst case analysis of the running time any algorithm would require. State-of-the-art solvers like CPLEX ¹, GUROBI ², XPRESS ³ use the simplex or the interior point algorithm combined with solution pruning methods as Branch and Bound or Branch and Cut, what makes them acquire relatively good average running times and makes LP a widely used method in operations research today. For example, for the TSP the optimal tour through 15112 Cities was calculated in 2001. [2]

Problem Definition

The Partition Coloring Problem is a generalization of the Standard Vertex Coloring Problem (VCP) and has initially been considered by Li and Simha in [21]. The problem arises from considering the joint problem of routing and wavelength assignment in Wavelength Division Multiplexing optical networks. It is therefore a subproblem of a variant of the Wavelength Routing and Assignment Problem (RWA), namely the min-RWA problem. This chapter aims to give formal definitions and examples of both, PCP and min-RWA and reason about their computational complexity.

3.1 Standard Vertex Coloring Problem

3.2 Partition Coloring Problem

As many Network Design Problems (NDPs), the VCP can be generalized by partitioning the vertex set V into clusters $V_k, k \in K$, and expressing feasibility constraints in terms of the clusters instead of individual nodes. [11] One resulting Generalized Network Design Problem (GNDP) is the PCP, which is due to Fereman's definition an "Exactly" GNDP, since it requires the solution to select exactly one vertex per each cluster. In contrast, "At Least" and "At Most" generalizations aim to select at least, respectively at most a given number of vertices per each cluster. A formal definition of PCP follows:

Let $G = (V, E)$ be a non-directed graph and V partitioned into q mutually exclusive, nonempty subsets V_1, V_2, \dots, V_q , where $V_i \cap V_j = \emptyset, \forall i, j = 1, \dots, q, i \neq j$. We refer to V_1, V_2, \dots, V_q as the components of the partition. The PCP consists in finding a subset $V' \subset V$ such that $|V' \cap V_i| = 1, \forall i = 1, \dots, q$ (i.e., V' contains one node of each component V_i), and the chromatic number of the graph induced in G by V' is minimum.

Figure 3.1: a) Shows a problem instance and b) its optimal solution with two colors.

Figure 3.1 shows an example of an instance with 5 clusters, each holding 2 nodes and its solution with a chromatic number of 2.

3.3 Wavelength Routing and Assignment Problem

Wavelength Division Multiplexing is a technique that allows a single optical link to transfer multiple datastreams simultaneously by using distinct wavelengths for each datastream. Data is transferred along a route of linked physical network routing devices (nodes). An all optical connection between two nodes is called lightpath. Assuming the so called wavelength continuity constraint [22] means to assume that the same wavelength has to be kept over all physical links along the route (i.e. it can not be converted by any node), so the lightpath has to be set up with one wavelength from the source to the destination node. It follows that any two paths, having at least one link in common, have to use different wavelengths, in order to enable the common link(s) to transfer data simultaneously. Figure 3.2 shows an extract of the European optical transport network.

In general, the Wavelength Routing and Assignment Problem (RWA) consists of an undirected network $G = (V, E)$, where nodes represent network routing devices and edges represent full duplex (optical) links, i.e. links supporting data transmission in both directions. Further, a set of source-destination pairs (or connection requests) $C = \{(s_1, d_1), \dots, (s_k, d_k) : s_i, d_i \in V\}$ and a set of wavelengths $\Lambda = \{\alpha_1, \dots, \alpha_m\}$ is given. If all connection requests are known in advance, the RWA is said to be static, otherwise dynamic. [6] The static RWA can further be distinguished by characteristics of its objective. In the context of this thesis, only the min-RWA problem is relevant, which is a static version of RWA aiming to select exactly one

Figure 3.2: Instance of an optical network with 57 vertices and 85 edges. Extracted from the European optical transport network. [4]

path and one wavelength for each pair $(s, d) \in C$, in the way that the number of wavelength $|\Lambda|$ is minimized under the continuity constraint and its consequences, i.e. if any two paths have at least one edge in common, distinct wavelengths have to be assigned to them. The problem can be split into two subproblems:

1. routing: finding a set of paths $P_{s,d}$ for each source-destination pair $(s, d) \in C$
2. wavelength assignment: selecting exactly one path in $P_{s,d}$ and one wavelength α_i for each pair $(s, d) \in C$, in the way that the number of wavelength is minimized under the continuity constraint.

Considering the demands of real world instances, it is clear that the computed paths should be relatively short. The first subproblem can be solved in polynomial time by any single source shortest path algorithms like Dijkstra's- or the B*-algorithm. If $|P_{s,d}| = 1, \forall (s, d) \in C$, i.e. there is exactly one path considered for each source-destination pair, the second subproblem can be transformed into VCP, in any other case $\exists (s, d) \in C : |P_{s,d}| > 1$ into PCP. The transformation consists in considering each source-destination pair (s, d) as a cluster and each path in $P_{s,d}$ as a node. In the case that two paths share at least one edge, the corresponding nodes are adjacent. Selecting a node-color pair out of a cluster in PCP is equivalent to selecting a path out of a to a node in PCP is equivalent to Figure 3.3 demonstrates the transformation by example.

Figure 3.3: a) A graph with two source-destination pairs and two paths each. Since paths p_2 and p_3 share edge $\{4,6\}$, they are not allowed to use the same wavelength and therefore the corresponding nodes are adjacent in b) the resulting PCP.

5.1 Constructional Heuristics

Algorithm 4: OneStepCD

Input: An uncolored Graph $G = (V, E)$

Output: A feasible Coloring V'

```
1 Remove from G all edges  $(i, j) \in E : i, j \in V_k$  for some  $k = 1, \dots, q$ ;
2 Set  $V' \leftarrow \emptyset$ ;
3 while  $|V'| < q$  do
4   Set  $X \leftarrow \emptyset$ ;
5   for  $k = 1, \dots, q : V_k \cap V' = \emptyset$  do
6     Set  $X \leftarrow X \cup \operatorname{argmin}\{CD(i) : i \in V_k\}$ ;
7   Set  $x \leftarrow \operatorname{argmax}\{CD(i) : i \in X\}$ ;
8   Set  $V' \leftarrow V' \cup \{x\}$ ;
9   Assign the minimum possible colour to x;
10  Remove from G all nodes in  $V_{c(x)} \setminus \{x\}$ ;
11 return  $V'$ ;
```

5.2 Recoloring

Random

OneStepCD

Algorithm 5: OneStepCD Recoloring

Input: A partial Solution P , a number of maximum colours $cmax$

Output: A feasible Solution S

```
1 Let  $U$  be the set of uncolored nodes in  $P$ ;  
2 Set  $S \leftarrow \emptyset$ ;  
3 while  $|U| > 0$  do  
4   Set  $X \leftarrow \emptyset$ ;  
5   for  $u \in U$  do  
6      $X \leftarrow X \cup \operatorname{argmin}\{CD(i) : i \in V_{c(u)}\}$ ;  
7   Set  $x \leftarrow \operatorname{argmax}\{CD(i) : i \in X\}$ ;  
8   Set  $cmin \leftarrow$  the minimum possible colour that can be assigned to  $x$ ;  
9   if  $cmin \geq cmax$  then  
10     $cmin \leftarrow$  the color that produces the fewest conflicts.  
11  Assign  $cmin$  to  $x$ ;  
12   $S \leftarrow S \cup \{x\}$ ;  
13   $U \leftarrow U \setminus V_{c(x)}$ ;  
14 return  $V'$ ;
```

ILP minimizing conflicts

Let $Q = Q_1, \dots, Q_q$ be the set of Clusters. Every cluster Q_p consists of a set of nodes. Let $C = \{1, \dots, cmax\}$ be the set of allowed colors. Let M be a 3-dimensional array of constants, storing for every cluster $p \in Q$, the number conflicts that would occur by selecting the pair $(v \in Q_p, c \in C)$. E denotes the set of edges and $P[v]$ the cluster of node v .

$$\underset{X}{\text{minimize}} \quad \sum_{p \in Q} \sum_{v \in Q_p} \sum_{c \in C} X_{pvc} * M_{pvc} \quad (1)$$

$$[h] \text{ subject to } \sum_{v \in Q_p} \sum_{c \in C} X_{pvc} = 1, \quad \forall p \in Q \quad (2)$$

$$X_{pvc} + X_{quc} \leq 1, \quad \forall ((p, v), (q, u)) \in E, \forall c \in C \quad (3)$$

$$X_{pvc} \in \{0, 1\}, \quad \forall p \in Q, \forall v \in Q_p, \forall c \in C \quad (4)$$

ILP minimizing conflicting nodes

Let U be the set of uncolored nodes in uncolored clusters and $color[(p, v)]$ the color of the node v in partition p .

$$\underset{Z}{\text{minimize}} \quad \sum_{p \in Q} \sum_{v \in Q_p} \sum_{c \in C} Z_{pvc} \quad (1)$$

$$\text{subject to } Z_{pvc} \geq X_{quc}, \quad \forall ((p, v), (q, u)) \in E : (p, v) \notin U, (q, u) \in U, c = color[(p, v)] \quad (2)$$

$$[h] \quad \sum_{v \in Q_p} \sum_{c \in C} X_{pvc} = 1, \quad \forall p \in Q \quad (3)$$

$$X_{pvc} + X_{quc} \leq 1, \quad \forall ((p, v), (q, u)) \in E, \forall c \in C \quad (4)$$

$$X_{pvc} \in \{0, 1\}, \quad \forall p \in Q, \forall v \in Q_p, \forall c \in C \quad (5)$$

5.3 Tabu Search

5.4 Variants

Algorithm 6: TabuSearch

Input: An infeasible solution S , the set of previously recolored nodes R , the set of conflicting nodes C

Output: A Solution \bar{S}

```
1 Set  $C \leftarrow C \setminus R$ ;  
2 Set  $cmax \leftarrow$  the chromatic number of  $S$ ;  
3 Set  $iter \leftarrow 0$ ;  
4 Set  $minConflicts \leftarrow \infty$ ;  
5 Set  $\bar{S} \leftarrow S$ ;  
6 while  $|C| > 0$  and  $iter < maxiter$  do  
7   for  $V_{c(u)} : u \in C$  do  
8     for  $v \in V_{c(u)}$  and for  $c = 1, \dots, cmax$  do  
9       Obtain a tentative solution  $S'$  by selecting and coloring node  $v$  with color  $c$  in  
        $\bar{S}$ ;  
10      if  $conflicts(S') = 0$  then  
11         $\bar{S} \leftarrow S', \bar{v} \leftarrow v, \bar{c} \leftarrow c$ ;  
12        goto line 16;  
13      else if the pair  $v, c$  is not in the tabu list then  
14        if  $conflicts(S') < minConflicts$  then  
15           $minConflicts \leftarrow conflicts(S')$ ;  
16           $\bar{S} \leftarrow S', \bar{v} \leftarrow v, \bar{c} \leftarrow c$ ;  
17    insert pair  $\bar{v}, \bar{c}$  in the tabu list for TabuTenure iterations;  
18     $C \leftarrow C \setminus u$ ;  
19    Let  $C_{\bar{v}}$  be the set of nodes conflicting with  $\bar{v}$ ;  
20     $C \leftarrow C \cup C_{\bar{v}}$ ;  
21 return  $\bar{S}$ ;
```

Computational Results

This chapter provides information about the implementation, testing environment, instances used for evaluation and the computational results. Different methods which have been presented in chapter 5 and various parameters are compared to each other and to results of [12, 21, 24].

6.1 Implementation Details and Testing Environment

The program has been implemented in Java and compiled with the JDK compiler version 1.7.0_25. For reasons of runtime comparability it has been designed to execute on a single thread, although the recoloring for each set of clusters of same color makes the program highly suitable to be processed in a parallel way. For the implementation of abstract data structures no other libraries than the ones provided by the JDK have been used. For solving the ILPs described in 5.4, ILOG CPLEX version 12.5 has been used, which is by now one of the fastest CP solvers available [3]. It is written in C++, provides facades to Java, Python, .NET, Matlab, Excel and supports comfortable usage of integer variables and a wide set of constraints and solving strategies. All tests have been performed on a Pentium i5 DualCore, 2.5 GHz, 8GB RAM, with Linux Mint 14 and OpenJDK Runtime Environment (IcedTea 2.3.9) installed.

6.2 Instances

Instances of different size, vertices per cluster ratio and density have been evaluated. Generated randomly and used by the authors of [12], the instances have also been evaluated in [29] and [9]. For reasons of better comparability to previous works, instances have been pooled to sets of same size respectively density. All of them contain 2 vertices per cluster. Furthermore four larger instances with constant density of 0.5, 500 clusters 1,2,3 and 4 vertices per cluster provided by the authors of [24] have been evaluated and compared.

6.3 Results

In the following section preliminarily and final results as well as comparison to results of previous works are presented. There have been preceding tests performed to select the most competitive ranges of parameters used in the tables.

Conflicting Vertices

As an intermediate result the numbers of conflicting vertices per each recoloring produced by the different recoloring algorithms have been recorded and compared to each other. Since for these experiments a constant length has been used for the tabu list, *HYBRID-PCP* is deterministic except the case when random recoloring is used. Therefore for random recoloring the average of ten runs per instance and recoloring has been calculated.

In tables 6.1 and 6.2 the results for sets of different size respectively density are presented. Each set contains five instances. Table 6.3 presents the results for the four larger instances. It can be seen that a large number of vertices and as well as a low density lead to a high amount of conflicts per recoloring. The difference between the results for *RANDOM* and *ILP2* grows to a factor of over 7.5 on the larger instances.

| Instance set | | Random (10 runs/inst) | OneStepCD | ILP1 | ILP2 |
|--------------|---------|-----------------------------|-----------------------------|-----------------------------|-----------------------------|
| vertices | density | <i>cvertices/recoloring</i> | <i>cvertices/recoloring</i> | <i>cvertices/recoloring</i> | <i>cvertices/recoloring</i> |
| 20 | 0.5 | 3.69 | 2.25 | 1.60 | 1.36 |
| 40 | 0.5 | 7.33 | 3.85 | 3.21 | 2.29 |
| 60 | 0.5 | 10.21 | 4.99 | 4.21 | 2.83 |
| 70 | 0.5 | 11.30 | 5.84 | 4.56 | 3.27 |
| 80 | 0.5 | 12.69 | 6.04 | 4.97 | 3.41 |
| 90 | 0.5 | 12.32 | 5.93 | 4.64 | 3.38 |
| 100 | 0.5 | 14.91 | 7.16 | 5.23 | 3.92 |
| 120 | 0.5 | 15.53 | 6.44 | 5.07 | 3.38 |

Table 6.1: Sets of different size containing five instances each. *cvertices/recoloring* denotes the average amount of conflicting vertices per recoloring.

| Instance set | | Random (10 runs/inst) | OneStepCD | ILP1 | ILP2 |
|--------------|---------|-----------------------------|-----------------------------|-----------------------------|-----------------------------|
| vertices | density | <i>cvertices/recoloring</i> | <i>cvertices/recoloring</i> | <i>cvertices/recoloring</i> | <i>cvertices/recoloring</i> |
| 90 | 0.1 | 15.71 | 9.50 | 6.61 | 5.65 |
| 90 | 0.2 | 16.70 | 7.99 | 6.36 | 4.87 |
| 90 | 0.3 | 15.94 | 7.60 | 5.48 | 4.03 |
| 90 | 0.4 | 14.73 | 6.16 | 4.75 | 3.41 |
| 90 | 0.5 | 13.51 | 5.93 | 4.94 | 3.43 |
| 90 | 0.6 | 11.78 | 5.20 | 4.39 | 2.84 |
| 90 | 0.7 | 9.60 | 4.61 | 3.90 | 2.44 |
| 90 | 0.8 | 7.70 | 3.66 | 3.04 | 2.05 |
| 90 | 0.9 | 5.56 | 2.69 | 2.34 | 1.74 |

Table 6.2: Sets of different density containing five instances each.

| Instance set | | Random (10 runs/inst) | OneStepCD | ILP1 | ILP2 |
|--------------|---------|-----------------------------|-----------------------------|-----------------------------|-----------------------------|
| vertices | density | <i>cvertices/recoloring</i> | <i>cvertices/recoloring</i> | <i>cvertices/recoloring</i> | <i>cvertices/recoloring</i> |
| 500 | 0.5 | 35.13 | 7.89 | 7.88 | 5.02 |
| 1000 | 0.5 | 39.87 | 9.15 | 7.74 | 5.15 |
| 1500 | 0.5 | 44.67 | 11.52 | 8.12 | 6.02 |
| 2000 | 0.5 | 46.81 | 12.29 | 4.75 | 6.42 |

Table 6.3: Evaluation of the four larger instances. *ILP2* produces about 7.5 times less conflicting vertices than *RANDOM*.

Final Results

For each set of instances experiments with various ranges of tabu list lengths as well as various boundaries for the maximum number of iterations have been performed. The size of the tabu list for each insertion is a random number between the lower and upper bound given as $TabuTenure$, where C' is the tentative number of colors. Because of that indeterminism 10 runs per instance have been performed. The maximum number of iterations used as stopping criterion is set as $maxIter = q * (C') * F_{end}$, where q is the amount of clusters. Tables 6.4 to 6.20 show the results of the instances provided in [12]. In tables 6.21 to 6.24 results of the large instances are shown, where the values of the parameters $TabuTenure$ and F_{end} have been chosen similar to the ones used in [24].

The final results do not exhibit an improvement similar to the preliminary results or any significant improvement at all. Especially on larger instances the difference between the runtimes of the exact and non-exact methods becomes visible. For most instances except the four large ones a $TabuTenure$ of $U[1.0C', 4.0C']$ and $U[0.0C', 5.0C']$ has shown to lead to best results. For the larger instances, a $TabuTenure$ of $U[0.0C', 0.5C']$ fits best, which approves the results in [24].

| Parameters | | Random | | | OneStepCD | | | ILP1 | | | ILP2 | | |

Table 6.24: Results for the instance *dsjc500.5-4*, 2000 vertices, density 0.5

Variants

As discussed in section 5.4, variants for both ILPs have been created by removing the inequation that restricts conflicts inside the recolored set of clusters. In tables 6.25 to 6.30 the standard ILPs marked as *ILP1* and *ILP2* are compared to their variants *ILP1** and *ILP2** by evaluating three instances of different size as well as three instances of different density. It can be seen that removing the aforementioned constraint does not increase the solution quality.

Furthermore experiments have been performed, placing the recently recolored set of clusters on the tabu list for a specified number of iterations. In tables 6.31 to 6.36 sets diversing in size and density have been evaluated using $F_{max} = 5$. The parameter *TTRecolored* sets the number of iterations as $Tabusize = TTRecolored * C'$ for all the vertex-color pairs of the recolored set of clusters to remain on the tabu list.

Table 6.36: ILP variants compared on a set of 5 instances with 120 vertices and a density of 0.5 each.

Comparison to previous works

Since *RANDOM* performs best in terms of runtime and is not significantly inferior to other methods in terms of quality, its results are compared to those of [12] and [29] in tables 6.37 and 6.38. In 6.39 results are compared to [24].

Table 6.39: in1

Critical Reflection and Outlook

7.1 Critical Reflection

Selecting and optimizing the coloring of a subset of clusters regardless of their location in the graph does not tackle the problem in an efficient way. The selection does not take into account any features of the graph like regional density, although dense subgraphs involve the most danger of increasing the chromatic number by being colored with a suboptimal coloring. Considering graph features being crucial for a good selection of clusters, the selection presented in this thesis is done in a random way and therefore an optimal, partial recoloring can not be integrated in the solution by the tabu search more probably than any random coloring.

7.2 Future Works

Future works could consider a more suggestive selection of the clusters to be recolored. Rather than selecting all clusters of the same color, the set could be chosen by criteria of regional density. Putting effort in optimizing the coloring of these regions – e.g. by the use of exact methods – could lead to results of higher quality.

On finding dense subgraphs

Finding dense subgraphs is a intensively studied problem in graph theory and became more relevant in recent years because of its application to social network graphs. As long as there are no boundaries set on the size of the densest subgraph, it can be found in polynomial time, despite the fact that there are exponentially many subgraphs to consider [20, 37]. Additionally, Charikar [7] showed a 2 approximation to the densest subgraph problem in linear time using a very simple greedy algorithm which was previously studied by Asahiro et. al. [36]). The densest k -subgraph problem (DkS), which finds the densest subgraph of size k is shown to be \mathcal{NP} -hard [32, 37]. For the densest at-most- k -subgraph problem ($DamkS$), which searches for the densest subgraph of maximum size k (and therefore is a relaxation of DkS), Andersen

et.al. [1] showed that if there exists a α approximation for *DamkS*, then there exists a $\mathcal{O}(\alpha^2)$ approximation for *DkS*, indicating that this problem is quite hard as well. Khuller and Saha showed that approximating *DamkS* is as hard as *DkS* within a constant factor [30], specifically an α approximation for *DamkS*, implies a 4α approximation for *DkS*. A number of polynomial time greedy heuristics for *DkS* are proposed in Asahiro et.al. [36].

Algorithm proposal

Algorithm 7 proposes a procedure for the discussed approach. The graph G , a recoloring algorithm *RECOLOR* like these presented in 5.2 and two integers used to parameterize the search for dense subgraphs are taken as input. In line 1 an initial solution is calculated and its chromatic number is assigned to $cmax$ in line 2. In line 3 an algorithm is called that returns up to $maxSubgraphs$ subgraphs with a maximum size of $denseMaxSize$. Line 4 to line 6 recolor all found subgraphs by applying *RECOLOR* and all remaining nodes colored with colors $cmax$ randomly, all with $cmax - 1$ colors. In line 8 the tabusearch tries to eliminate all resulting conflicts and puts the recolored regions on the tabulist for a number of iterations as presented in [TODO]. Line 9 to 11 accept the new solution in case of feasibility and starts searching for dense regions again.

Algorithm 7: PCP HYBRID DENSERECOLORING

Input: An uncolored Graph $G = (V, E)$, a recoloring-algorithm *RECOLOR*, two integers $maxSubgraphs$ and $denseMaxSize$

Output: A feasible Solution S

- 1 Set $S \leftarrow ONESTEP CD(G)$;
 - 2 Set $cmax \leftarrow$ the chromatic number of S ;
 - 3 Set $D \leftarrow FINDDENSESUBGRAPHS(S, maxSubgraphs, denseMaxSize)$;
 - 4 Let S' be the solution after recoloring all subgraphs in D with *RECOLOR* and $cmax - 1$ colors;
 - 5 Let R be the set of all remaining nodes in V colored with $cmax$;
 - 6 Let S' be the solution after recoloring R randomly with $cmax - 1$ colors;
 - 7 Let C' be the set of nodes involved into color conflicts in S' ;
 - 8 $S' \leftarrow TABUSEARCH(S', D \cup R, C')$;
 - 9 **if** S' is free of conflicts **then**
 - 10 $S \leftarrow S'$;
 - 11 **goto** line 2;
 - 12 **return** S ;
-

Summary

The PCP is a quite recently proposed COP which generalizes the classical VCP by considering the possibility to select subsets of vertices. While for the VCP much research has been done, only a few papers about the PCP has been published so far. In this work a strategy is presented that creates an initial solution by a heuristical algorithm and improves the solution quality by recoloring sets of vertices of same color before eliminating the resulting conflicts by applying a tabu search. It has been tried to enhance the algorithm presented in [24] by substituting the process of random recoloring by more sophisticated algorithms in order to minimize the number of resulting conflicts. Therefor a variation of the *ONESTEP*CD algorithm [21] and two ILPs were used. A local search algorithm then tries to eliminate all these conflicting vertices to create a feasible solution. Furthermore experiments with variations of the ILPs and a mechanism that puts the most recently recolored subgraph on the tabulist for an amount of iteration in order to protect the coloring of that subgraph from being overwritten have been done.

The results have shown that more sophisticated recoloring algorithms can reduce the number of conflicts dramatically. For the instances used, a random recoloring produces an amount of conflicting vertices up to 7.5 times higher than an optimized recoloring does. The fact that this gap is not reflected significantly in the final results leads to the conclusion that for the presented strategy the tabu search is much more relevant than the recoloring process. Finally an alternative strategy, that is suspected by the author to be more suitable for sophisticated recoloring methods has been proposed.
